

## Confidence Intervals

### Confidence Interval Dynamics

1. Exploring the role of sample size With 95% level ( $\alpha = 0.05$ ) and  $s = 0.9$ , the half-width is

$$\text{half-width} = t^* \frac{s}{\sqrt{n}}, \quad t^* = t_{0.025, df}, \quad df = n - 1.$$

Using standard  $t$ -quantiles:

- $n = 3$  ( $df = 2$ ):  $t^* \approx 4.303 \Rightarrow \text{half-width} \approx 1.295$
- $n = 5$  ( $df = 4$ ):  $t^* \approx 2.776 \Rightarrow \text{half-width} \approx 1.118$
- $n = 10$  ( $df = 9$ ):  $t^* \approx 2.262 \Rightarrow \text{half-width} \approx 0.643$
- $n = 15$  ( $df = 14$ ):  $t^* \approx 2.145 \Rightarrow \text{half-width} \approx 0.498$
- $n = 20$  ( $df = 19$ ):  $t^* \approx 2.093 \Rightarrow \text{half-width} \approx 0.421$
- $n = 30$  ( $df = 29$ ):  $t^* \approx 2.045 \Rightarrow \text{half-width} \approx 0.336$

2. Confidence level and  $t^*$

- a) Fix  $n = 10$  ( $df = 9$ ),  $s = 0.9$ ; two-tailed  $t^*$ :

- 80%:  $t_{0.10,9} \approx 1.383$
- 90%:  $t_{0.05,9} \approx 1.833$
- 95%:  $t_{0.025,9} \approx 2.262$
- 99%:  $t_{0.005,9} \approx 3.250$

- b) Higher confidence  $\Rightarrow$  smaller  $\alpha \Rightarrow$  fatter central region  $\Rightarrow$  larger quantile  $t^*$ ; hence  $2 t^* \frac{s}{\sqrt{n}}$  increases with the level.

- c) Width ratio (same  $n, s$ ) is the ratio of the two values of  $t^*$ :

$$\frac{\text{width}_{99\%}}{\text{width}_{90\%}} = \frac{t_{0.005,9}}{t_{0.05,9}} \approx \frac{3.250}{1.833} \approx 1.77.$$

### 3. Trade-off between variability and sample size

a) At 95%, half-width =  $t^* \frac{s}{\sqrt{n}}$ .

- $(n, s) = (8, 0.6)$ :  $df = 7$ ,  $t^* \approx 2.365$ , so half-width  $\approx 2.365 \cdot \frac{0.6}{\sqrt{8}} \approx 0.502$

- $(n, s) = (20, 1.0)$ :  $df = 19$ ,  $t^* \approx 2.093$ , so half-width  $\approx 2.093 \cdot \frac{1.0}{\sqrt{20}} \approx 0.468$

Thus  $(8, 0.6)$  is (slightly) wider—smaller  $n$  and larger  $t^*$  outweigh the smaller  $s$ .

b) Keep  $s = 0.9$ , level 95%. Need  $t^* \frac{0.9}{\sqrt{n}} \leq 0.30$ . Using  $t_{0.025, n-1}$ , the smallest  $n$  that satisfies

this is about  $n \approx 37$  (since  $t_{0.025, 36} \approx 2.03$  gives  $2.03 \cdot 0.9/\sqrt{37} \approx 0.30$ ).

c) Hold  $n = 12$  ( $df = 11$ ), level 90% so  $t^* = t_{0.05, 11} \approx 1.796$ . Full width = 0.9 means

$$2 t^* \frac{s}{\sqrt{12}} = 0.9 \Rightarrow s = \frac{0.9 \sqrt{12}}{2 t^*} \approx \frac{0.9 \cdot 3.464}{2 \cdot 1.796} \approx 0.868.$$

### Calculations

1. A researcher is analysing individuals' relative fear of being a victim of burglary on a 1-100 scale. A random sample of 9 individuals found a mean score of 47 on the scale with a sample variance of 158.76 for fear of being burgled.

a. What distribution would be used to calculate an 80% confidence interval around this mean?

A t-distribution as we don't know the population standard deviation and  $n$  is small.

b. Construct that interval.

$$\bar{x} = 47$$

$$n = 9$$

$$t \text{ from tables} = 1.397$$

$$s = \sqrt{158.76}$$

$$s = 12.6$$

Confidence interval formula

$$\bar{x} \pm t \times \frac{s}{\sqrt{n}}$$

Lower bound

$$47 - 1.397 \times \frac{12.6}{\sqrt{9}} = 47 - 5.867 = 41.13$$

Upper bound

$$47 + 1.397 \times \frac{12.6}{\sqrt{9}} = 47 + 5.867 = 52.87$$

2. We are investigating the height of men in the UK. For this we have obtained a random sample of 100 UK men and found they had a mean height of 180cm with a standard deviation of 10cm.
- a. Construct a 95% confidence interval for the mean height of UK males.

$$\bar{x} = 180$$

$$s = 10$$

$$n = 100$$

As the population standard deviation is not known, the t distribution and t need to be used.

Find the t-score for a 95% confidence interval in the t-table with 99 df.

$$t = 1.984$$

Confidence interval:

$$\bar{x} \pm t \times \frac{s}{\sqrt{n}}$$

Lower bound:

$$180 - 1.984 \times \frac{10}{\sqrt{100}} = 180 - 1.984 = 178.02$$

Upper bound:

$$180 + 1.984 \times \frac{10}{\sqrt{100}} = 181.98$$

- b. Select all true statements concerning the constructed confidence interval and justify your choice for each statement.
- The probability of the population mean being within the upper and lower bounds is 95%.  
FALSE - The population mean is fixed but unknown and therefore can either be inside the bounds or outside. The Probability is therefore 50%.
  - 95% of men's heights fall between the upper and lower bound.  
FALSE - The distribution calculated is not the distribution of men's height, but the sampling distribution of the mean male height.
  - 95% of the cases in the sample fall between the upper and lower bound.  
FALSE - The distribution calculated is not of men's height in this sample, but the sampling distribution of the mean male height.
  - On average 95% of confidence intervals constructed would contain the population mean.  
TRUE

- v. On average 95% of the means of samples with 100 respondents will fall within the upper and lower bands.  
FALSE - This confidence interval is not making statements about various sample means but rather about the population mean.
- vi. On average 95% of the sample means equal the population mean.  
FALSE - The confidence interval is a range and does not make claims about where the population mean is exactly.

## Significance Testing

### Exercises – The t-distribution

#### 1. How $df$ changes the shape and critical values

Using two-tailed,  $\alpha = 0.05$  (so  $t_{\text{crit}} = t_{0.025, df}$  with  $df = n - 1$ ):

- $n = 3$  ( $df = 2$ ):  $t_{\text{crit}} \approx 4.303$
- $n = 5$  ( $df = 4$ ):  $t_{\text{crit}} \approx 2.776$
- $n = 10$  ( $df = 9$ ):  $t_{\text{crit}} \approx 2.262$
- $n = 20$  ( $df = 19$ ):  $t_{\text{crit}} \approx 2.093$
- $n = 50$  ( $df = 49$ ):  $t_{\text{crit}} \approx 2.009$

The normal reference is  $z_{0.025} \approx 1.960$ .

Within 0.05 of 1.96 occurs by  $n \approx 50$  ( $df = 49$ , 2.009 is 0.049 above 1.96).

Explanation: as  $df \rightarrow \infty$ , the  $t$  distribution  $\rightarrow N(0, 1)$ , so tails thin and  $t_{\text{crit}}$  decreases toward 1.96.

#### 2. One-tailed vs two-tailed critical regions

With  $df = 14$  and  $\alpha = 0.05$ :

- Two-tailed:  $t_{0.025, 14} \approx 2.145$ , cut points at  $\pm 2.145$
- One-tailed (upper):  $t_{0.05, 14} \approx 1.761$ , single cut point at  $+1.761$

For  $H_0 : \mu = \mu_0$  vs  $H_1 : \mu > \mu_0$ , the one-tailed threshold  $t_{0.05, 14}$  is relevant because only the upper tail provides evidence against  $H_0$ .

In both cases, the shaded area equals  $\alpha$ :

- two-tailed shades two symmetric regions each of area  $\alpha/2$ ;
- one-tailed shades a single upper tail of area  $\alpha$ .

## Effect size, sample size, and power

1. Same effect size, different  $n$  (mapping  $t$ ,  $n$ , and  $\hat{d}$ )
  - a. With  $t = 1.6$  and  $n = 16$ ,  $\hat{d} = t/\sqrt{n} = 1.6/4 = 0.40$ . The power at  $n = 16$  for  $\hat{d} \approx 0.40$  and  $\alpha = 0.05$  will be modest (typically well below 0.80).
  - b. Keeping  $\hat{d}$  fixed at 0.40 and raising  $n$  to 64 requires  $t = \hat{d}\sqrt{n} = 0.40 \times 8 = 3.2$ . The app will show the same  $\hat{d}$  but a higher power at  $n = 64$ .
  - c. As  $n$  increases while the underlying effect stays fixed, the standard error shrinks:  $SE = s/\sqrt{n}$ . The test statistic is  $t = \frac{\bar{X} - \mu_0}{SE}$ , so a smaller SE makes  $|t|$  larger on average. For a fixed  $\alpha$ , the critical cutoff (e.g.,  $t_{\alpha/2, df}$  for a two-sided test) is essentially fixed, so larger typical  $|t|$  increases the chance that  $|t| > t_{\alpha/2, df}$ . Therefore, bigger  $n \Rightarrow$  less sampling noise  $\Rightarrow$  tighter estimates  $\Rightarrow$  higher power.
2. Planning with a SESOI and  $\alpha$  sensitivity
  - a. For  $t = 2.0$  and  $n = 30$ ,  $\hat{d} = t/\sqrt{n} \approx 2.0/\sqrt{30} \approx 0.37$ . The app will report the power at  $n = 30$  using this  $\hat{d}$  (typically moderate at  $\alpha = 0.05$ ).
  - b. Turning on the SESOI with  $d = 0.5$  switches the curve to a fixed target effect. The orange marker shows the  $n$  giving 80% power at  $\alpha = 0.05$ ; for  $d = 0.5$  this is typically in the few-dozen range for a one-sample  $t$ -test (on the order of the 30s).
  - c. Increasing  $\alpha$  to 0.10 lowers the critical threshold and reduces the required  $n$  for a given power; decreasing  $\alpha$  to 0.01 raises the threshold and increases the required  $n$ . Formally, stricter  $\alpha$  increases the critical  $t$  value, so a larger  $n$  is needed for the same probability of exceeding it under the alternative.
3. Was the study well powered? Post-hoc check and replication planning
  - a. With  $t = 2.1$  and  $n = 25$ ,  $\hat{d} = 2.1/\sqrt{25} = 2.1/5 = 0.42$ . The app will show the power at  $n = 25$  for  $\hat{d} \approx 0.42$  and  $\alpha = 0.05$ ; this is typically only moderate, not comfortably high.
  - b. For replication planning, turn on SESOI and choose the closest option to  $\hat{d}$  (e.g.,  $d = 0.5$ ). The orange marker will give the  $n$  needed for 80% power at the chosen  $\alpha$ ; expect a sample size in the few-dozen range for  $d = 0.5$  at  $\alpha = 0.05$ .
  - c. A significant result with low power can be fragile because small shifts in sampling may miss the effect and estimates are noisier. Picking a SESOI (a target  $d$  tied to practical importance) and planning for 80% power helps ensure a replication has adequate sensitivity to detect a meaningfully sized effect.

### Summarising Conclusions

- Power is the probability your test will detect a real effect (reject  $H_0$  when the effect truly exists).
- The curve fixes an effect size  $d$  and shows how power increases with  $n$ .
- If you base  $d$  on your observed test ( $\hat{d} = t/\sqrt{n}$ ), the curve answers: "If the effect really was the size we observed, how likely would the test be to detect that effect at other sample sizes  $n$ ?"
- If you base  $d$  on a meaningful minimum (SESOI), the curve answers: "How large should  $n$  be to reliably detect an effect that actually matters?"
- The 0.80 (80%) line is a convention (not a law). Many fields use it as a planning minimum; higher power (e.g., 90%) is desirable when stakes are high.
- Rule of thumb: because  $t = d\sqrt{n}$ , halving  $d$  requires about 4× the sample size to keep power roughly the same.

### Why do many plots show an 80% power line?

- 80% power means choosing  $\beta = 0.20$  (so power =  $1 - \beta = 0.80$ ). This is a planning convention, not a mathematical law.
- The convention became common through methodological guidance (e.g., Cohen's power analysis texts) and is echoed in many applied fields.
- In higher-stakes settings (e.g., confirmatory clinical trials), targets of 80–90% power are typical; 90
